

Tenjing Norsang

MTEC 2280 Final

My final project is a music player. It has two LEDs, one to indicate that it is on, and one that lights up when a note is played while a song is playing. A piezo plays the music. A button stops a song if one is playing. You can adjust the speed of the song with a potentiometer. Everything is encased within a foam box with holes made for the usb cable, button, and potentiometer. On the digital side, there is a user interface in javascript that allows the user to pick a song. It has some particle effects in the background that change colors depending on the song. The way it works technically is that the microcontroller waits for a signal from the server to tell it which song to play. When a user chooses a song, the microcontroller receives a specific signal and plays the corresponding song. From there the user can adjust the speed of the song with the potentiometer or stop playing with the button.
